4. (8 points) Spring Pruning

Fill in the function `prune` below so that given a Tree (see page 2) with integer labels, it (destructively) deletes all nodes whose label is strictly less than that of their parent if their parent is at even depth, or whose label is strictly greater than that of their parent if their parent is at odd depth. Deleting a node deletes the entire subtree below it. The root of the entire tree is at depth 0. For example, given the tree on the left, your function should produce the tree on the right without creating any new Tree nodes. The function `prune` does not return a value.

Spring
2017

Final Q4 2

```
def prune(t):
    def prune_level(t, d):
        if d % 2 == 0:
            t.branches = [b for b in t.branches if b.label >= t.label]
        else:
            t.branches = [b for b in t.branches if b.label <= t.label]
        for b in t.branches:
            prune_level(b, d+1)
    prune_level(t, 0)
```

Fall 2016
Midterm I
Q2

A complete answer will:

- Code Snippet:**

```

1 def splash(klay, curry):
2   while curry == 3:
3     steph = klay
4     klay = lambda klay: steph(curry + 1)
5     curry = curry + 2
6   return klay
7   return curry // 5
8
9 steph = lambda klay: splash(11, curry)
10 steph, curry = splash(steph, 30)
11 steph(4)

```

Execution Frames:

 - Global frame**
 - splash
 - f1: splash** (parent=Global)
 - klay: 11
 - curry: 30
 - Return Value: 6
 - f2: λ** (parent=f1)
 - klay: 4
 - curry: 3
 - Return Value: 3
 - f3: λ** (parent=f2)
 - klay: 6
 - curry: 3
 - Return Value: 3
 - f4: splash** (parent=f3)
 - klay: 11
 - curry: 30
 - Return Value: 6

Annotations:

 - Red arrows indicate the flow of execution and the return of values.
 - Handwritten notes: "func $\lambda(klay)$ P = G line 9" and "func $\lambda(klay)$ P = f1 line 4".

Summer
2015
final Q1

berkeley.edu

1. (14 points) What Would Scheme Do?

Assume that you have started the interactive Scheme interpreter from Project 4 using `python3 scheme.py` and executed the following statements:

```
(define lst '(1 2 (+ 3 4)))  
(define y 1)  
(define f (mu (x) (+ x y)))  
(define g (lambda (x y) (f (+ x x))))  
(define (h z) (z 3 7))
```

(if (print 5) #t

→ 2

3)

5

X

For each of the expressions in the table below, write the output displayed by the interpreter when the expression is evaluated. If an error occurs, write "Error". Assume each is executed in the same interactive session started above; the result of executing one line may affect the result of other lines.

Expression	Interactive Output
<code>(+ 1 2 3)</code>	6
<code>(/ 1 0)</code>	Error
<code>lst</code>	(1 2 (+ 3 4))
<code>(car (cdr lst))</code>	2
<code>(cons (cons 3 (cons 4 nil)) 5)</code>	
<code>(or 1 (/ 1 0))</code>	1
<code>(and 1 (/ 1 0))</code>	Error
<code>(h +)</code>	
<code>(define x 5)</code>	#undefined
<code>(f (+ x x))</code>	#f
<code>(h g)</code>	
<code>(let ((a 1) (2 2)) a)</code>	
<code>(let ((x 1) (y x)) y)</code>	
<code>(f y)</code>	

3. (6 points) Max Tree

- (a) (4 pt) Implement `max_tree`, which takes a `Tree` instance `t` and a function `key` that takes one argument and returns a number. The `max_tree` function returns the label `n` of `t` for which `key(n)` is largest. If there is more than one label for which `key` returns the same largest value, `max_tree` can return any of those labels. The `Tree` class is defined on the Midterm 2 Study Guide. You may not call `min` or `max`.

```
def max_tree(t, key):
    """Return the label n of t for which key(n) returns the largest value.

    >>> t = Tree(6, [Tree(3, [Tree(5)]), Tree(2), Tree(4, [Tree(7)])])
    >>> max_tree(t, key=lambda x: x)
    7
    >>> max_tree(t, key=lambda x: -x)
    2
    >>> max_tree(t, key=lambda x: -abs(x - 4))
    4
    """
    if t.is_leaf():
```

```
        return t.label
```

```
    x = t.label
```

```
    for b in t.branches:
```

```
        m = max_tree(b, key)
```

```
        if key(x) < key(m):
```

```
            x = m
```

```
    return x
```

label

largest
value

label
in the
tree

x is a
label in the
tree

- (b) (2 pt) Now implement `max_tree` in one line using a call to the built-in `max` function.

You may not include any additional calls to `max` beyond the one included in the template below.

```
def max_tree(t, key):
    """Return the label n of t for which key(n) returns the largest value."""
```

```
    return max([t.label] + [max_tree(b, key) for b in t.branches], key=key)
```
